

SUMMER-16 EXAMINATION

Model Answer

Subject code :(17426)

Page 1 of 25

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

| | | | |
|------|---|---|---|
| |  <p>The diagram illustrates the internal components of a centrifugal pump. A vertical shaft, labeled 'Stem', passes through the center of the pump body. The shaft is shown in two positions: a solid line representing the 'Fully open position' and a dashed line representing a closed position. The pump body is shown with a 'Plug' at the bottom, which can move horizontally as indicated by a double-headed arrow. The pump is mounted on a base.</p> | 4 | |
| 1B-c | <p>Working of centrifugal pump:</p> <p>Once the trapped air in pump is removed (priming), the delivery valve is kept closed & power from electric motor is applied to the shaft. The delivery valve is kept closed to reduce the starting torque for motor. The impeller rotates within the casing, which produces the forced vortex & it imparts a centrifugal head to the liquid. The pressure throughout the liquid is increased. When delivery valve is opened, the liquid is made to flow in an outward radial direction thereby leaving the vanes of the impeller at the outer circumference of the impeller with high velocity & pressure.</p> <p>Due to centrifugal action, a partial vacuum is created at the eye of impeller. This causes the liquid from sump to rush through the suction pipe to the eye of impeller. From the eye, the liquid flow through the vanes and reach the tip of the vanes. From the tip of the vanes, the liquid enters a casing where the kinetic energy of the fluid is converted to pressure energy. This pressure</p> | 4 | 4 |

SUMMER-16 EXAMINATION

Model Answer

Subject code :(17426)

Page 10 of 25

It states that the shear stress on a layer of fluid is directly proportional to the rate of shear.

Derivation:

Consider two layer of fluid 'y' cm apart as shown in fig. let the area of each of these layer be $A \text{ cm}^2$. Assume that top layer is moving parallel to the bottom layer at a velocity $u \text{ cm/s}$ relative to the bottom layer. To maintain this motion i.e. the velocity 'u' and to overcome the fluid friction between these layers, for any actual fluid, a force of 'F' dyne is required.

Experimentally it has been found that the force F is directly proportional to the velocity u and area A and inversely proportional to the distance y.

Therefore , mathematically it becomes

$$F \propto u.A/y$$

Introducing a proportionality constant μ ,

$$F = \mu u A/y$$

$$F/A = \mu u/y$$

Shear stress , τ equal to F/A between any two layers of fluid may be expressed as

$$\tau = F/A = \mu .u/y$$

The above equation in a differential form becomes

$$\tau = \mu \cdot \frac{du}{dy} \quad \dots\dots \text{eq}^n \text{ Newton's law of viscosity.}$$

3-f

Characteristic curves of a centrifugal pump :

The H-Q curve shows the relationship between head and capacity rate .it is clear from the curve that the head decreases continuously as the discharge rate is increased. The optimum conditions for operation are those at which the ordinate through the point of maximum efficiency cuts the head curve. The point A is called as duty point.

The head corresponding to zero or no discharge is known as the shut off head of the pump. From H-Q curve, it is possible to determine whether the pump will handle the necessary quantity of liquid against a desired head or not and the effect of increase or decrease of head. The PB- Q curve gives us an idea regarding the size of motor required to operate the pump at the required conditions and whether or not motor will be overloaded under any other operating conditions. The η-Q curve shows the relationship between pump efficiency and capacity. It is clear from η-Q curve that efficiency rises rapidly with discharge at low discharge rate, reaches a maximum in the region of the rated capacity and then falls.

| | <p>As per Newton's law of viscosity ,viscosity is shear stress required to produce unit rate of shear deformation.</p> $\mu = - \frac{\tau}{\frac{du}{dr}} \quad eq.1$ <p>The negative sign in the above equation is due to the fact that in a pipe velocity decreases with increase in radius.</p> <p>Rearranging the eq.1</p> $\frac{du}{dr} = - \frac{\tau}{\mu} \quad eq.2$ <p>As the linear relation between shear stress (τ) and radius (r) is</p> $\frac{\tau_w}{r_w} = \frac{\tau}{r}$ <p>Therefore $\tau = \frac{\tau_w}{r_w} \cdot r \quad eq.3$</p> <p>Substituting value of τ from eq.3 in eq.2,</p> $\frac{du}{dr} = \frac{\tau_w}{r_w \cdot \mu} \cdot r$ $du = \frac{\tau_w}{r_w \cdot \mu} \cdot r \cdot dr \quad eq.4$ <p>Integrating eq.4 with the boundary condition ,at $r = r_w$: $u = 0$ we get</p> $\int_0^u du = - \frac{\tau_w}{r_w \cdot \mu} \int_{r_w}^r r \cdot dr$ $u = - \frac{\tau_w}{r_w \cdot \mu} \left[\frac{r^2}{2} \right]_{r_w}^r$ $u = \frac{\tau_w}{2 \cdot r_w \cdot \mu} [r_w^2 - r^2] \quad eq.5$ <p>At the center of the pipe : $r = 0$. $u = u_{max}$.</p> $u_{max} = \frac{\tau_w r_w}{2 \cdot \mu} \quad eq.6$ | <p>2</p> <p>2</p> | |
|--|--|-------------------|--|

SUMMER-16 EXAMINATION

Model Answer

Subject code :(17426)

Page 17 of 25

Substituting the value of shear stress as

$$\tau_w = \frac{\Delta P \cdot r_w}{2\Delta L} \text{ in eq.6}$$

$$u_{max.} = \frac{\Delta P \cdot r_w^2}{4 \cdot \mu \cdot \Delta L}$$

As $D = r_w / 2$

$$u_{max.} = \frac{\Delta P \cdot D^2}{16 \cdot \mu \cdot \Delta L}$$

From equations 5 and 6,

$$u = u_{max.} \left[1 - \left(\frac{r}{r_w} \right)^2 \right]$$

The average velocity u of the entire stream flowing through any given cross-

section (A) is defined as $u = \frac{1}{A} \int u \cdot dA$ eq.7

As $A = \pi r_w^2$, $dA = 2 \pi r \cdot dr$ = area of elementary ring of radius r and width dr . Putting values of A, u and dA in eq.7, we get

$$u = \frac{\tau}{r_w^3 \cdot \mu} \int_0^{r_w} (r_w^2 - r^2) \cdot r \cdot dr$$

$$u = \frac{\tau_w r_w}{4\mu} \quad \text{eq. 8}$$

Therefore $\frac{u}{u_{max.}} = 0.5$

Eliminating τ_w by replacing it by ΔP , using $\tau_w = \frac{\Delta P \cdot r_w}{2\Delta L}$ and replacing r_w by $D/2$ in eq, we get

$$u = \frac{\Delta P \cdot D^2}{32 \cdot \mu \cdot \Delta L} \quad \text{eq. 9}$$

| 6-a | <p>Single acting reciprocating Pump Construction :</p> <p>Reciprocating pump consists of a piston or plunger which reciprocates in stationary cylinder. The cylinder is connected to suction and delivery pipes. Each of these pipes are provided with a non-return valve called as a suction & delivery valve respectively .The non-return valve permits unidirectional flow. The suction valve permits the liquid to enter into pipe only while the delivery valve allows the discharge of liquid from the cylinder. A piston or plunger is connected to a crank by means of a connecting rod. The crank is rotated by a driving engine or electric motor. When crank is rotated by the drive, the piston or plunger moves to and fro in the cylinder. Air vessels are provided at the discharge end to even out the discharge of liquid. Air vessels also reduce the frictional losses in pump. In case of single acting reciprocating pump, the liquid is in contact of with only one side of a piston or a plunger.</p> <p>Diagram</p> | 4 | 8 |

| <p>or gas as a motive force. Very often, the motive fluid is steam and the device is called a “steam jet ejector.” Basic ejector components are the steam chest, nozzle, suction, throat, diffuser and they discharge. An ejector has two inlets: one to admit the motive fluid, usually steam (inlet 1), and the other to admit the gas/vapor mixture to be evacuated or pumped (inlet 2).</p> <p>Motive steam, at high pressure and low velocity, enters the inlet 1 and exits the steam nozzle at design suction pressure and supersonic velocity, entraining the vapor to be evacuated into the suction chamber through inlet 2. The nozzle throat diameter controls the amount of steam to pass through the nozzle at a given pressure and temperature.</p> <p>The entrained gas/vapor flow and the motive fluid (steam) flow mix while they move through the converging section of the diffuser, increasing pressure and reducing velocity. The velocity of this mixture is supersonic and the decreasing cross sectional area creates an overall increase in pressure and a decrease in velocity. The steam slows down and the inlet gas stream picks up speed and, at some point in the throat of the diffuser, their combined flow reaches the exact speed of sound. A stationary, sonic-speed shock wave forms there and produces a sharp rise in absolute pressure. Then, in the diverging section of the diffuser, the velocity of the mixture is sub-sonic and the increasing cross sectional area increases the pressure but further decreases the velocity.</p> <p>Diagram</p> | <p>5</p> | |
